Design justification

A focused mobile companion for incident investigation and verified fix review.

Purpose and intended user

Aegis Mobile is designed for an on-call engineer who needs to understand an incident away from a desktop. The interface brings the incident, verification evidence and proposed GitHub change into one short journey. The goal is informed human review; passing a sandbox test is never presented as a production deployment.

Visual direction

The approved design adapts the GitHub mobile patterns supplied as visual references: generous white space, rounded grouped lists, strong page titles, compact status labels and a floating bottom navigation bar. Familiar code-review patterns help the target user recognize incidents and proposed fixes quickly. The black guardian mascot gives Aegis its own identity through an ancient helmet/guardian motif, replacing the earlier shield.

Element	Decision and rationale
Palette	White and pale gray surfaces keep technical content readable. Black anchors the logo and primary sign-in action. Blue identifies navigation and links. Red marks high priority; amber marks medium priority; purple identifies verification; green identifies a verified candidate or proposed fix.
Typography	Inter provides a consistent sans-serif hierarchy across editable Figma text. Larger headings identify the current task; secondary text carries service, time and context. Long code belongs in a dedicated review surface.
Components	Rounded list groups, recognizable icons, severity labels and persistent navigation reduce repeated orientation. Color is paired with words or symbols so severity is not conveyed by color alone.

Landing motion

Only the sign-in screen animates. The guardian appears through a short fade, rise and scale reveal, followed by the Aegis name and sign-in controls over about three seconds. Other screens remain still. A reduced-motion implementation should show the final state immediately and avoid delaying authentication.

Design decisions in context

How the six approved screens support a coherent engineering workflow.

Screen	User need and design response
01 · Sign in	GitHub sign-in is the primary concept because review ends in GitHub. Work-email access is a secondary option. Terms and Privacy labels are visible; the authentication service and legal destinations remain to be implemented.
02 · My Work	Lists active incidents, proposed fixes, verification runs, monitored services and activity logs. A priority queue places high-severity incidents before medium-severity incidents.
03 · Inbox update	Presents one incident as an agent update: service, symptoms, provisional diagnosis and verification checks. Inbox is the selected bottom tab.
04 · Queue review	Uses red/green diff conventions to show a proposed change and recorded evidence. Queue is selected. The action opens GitHub for human review; the SQL shown is illustrative.
05 · Agent conversations	Uses a conversation-list layout with contextual incident threads. Future agents are visibly labeled Coming soon rather than presented as functioning capabilities.
06 · Agent chat	Shows an incident-linked question and evidence-based reply, a proposed-fix action and message composer. Chat is a prototype concept, not an implemented backend connection.

Readability, accessibility and safeguards

The proposed implementation should provide at least 44 logical-pixel touch targets, scalable text, screen-reader labels for icon controls and sufficient text contrast. These are implementation acceptance criteria, not a claim of a completed accessibility audit. Failure, empty, stale-data and disconnected states must preserve the incident context and provide a clear recovery action.

Scope and attribution

The current Figma prototype demonstrates selected navigation with sample data. GitHub OAuth, message sending, search and full secondary states are not complete product features. GitHub/Mobbin screenshots informed layout; the new mascot was generated as an editable vector using Figma AI. Upstream backend authorship remains credited to Ahmed Harib.
